Protect Yourself from Bites

Even though your property may be devoid of mosquito breeding sites, mosquitoes can travel two to three miles from their breeding sites in search of a blood meal. Following these tips can reduce your risk of being bitten by mosquito repellents.

● Make sure window and door screens are “bug tight.”
● Use the proper type of light outside; incandescent lights attract mosquitoes, while fluorescent lights neither attract nor repel mosquitoes.
● Stay indoors at dawn and dusk, when mosquitoes are most active. If you must go outdoors, wear a long-sleeved shirt and long pants.
● Insect repellents, when applied (sparingly) to exposed skin, deter mosquitoes from biting. Spray thin clothing with repellent since mosquitoes can bite through it. Be sure to follow all directions on product label.
● In April 2005, the Centers for Disease Control and Prevention released new guidance about effective mosquito repellents. In addition to DEET, two additional active ingredients, picaridin and oil of lemon eucalyptus, have been shown to offer long-lasting protection.

How to Submit a Dead Bird

The Commonwealth of Pennsylvania is strongly encouraging citizens to report and submit dead birds for West Nile virus. Reporting can be done online, while submission must be done through county West Nile virus coordinators. All species of birds, except chickens and water fowl, will be tested. However, only a limited number of birds will be tested each week. The information you provide is important and will be entered into a database for tracking purposes since birds provide an early warning that the virus is active in an area. For more information, visit the Pennsylvania Department of Health Web site at www.westnile.state.pa.us or call toll-free 1-877-PA-HEALTH (724-3258).

West Nile Virus

The West Nile virus, which can cause encephalitis, is commonly found in humans, birds, and other animals in Africa, Europe, Asia, and the Middle East. The virus was first isolated in the West Nile province of Uganda in 1937. The earliest recorded epidemics of West Nile encephalitis occurred in Israel between 1951 and 1954 and again in 1957. Since the mid-1990s, the frequency and severity of West Nile virus outbreaks have increased. West Nile encephalitis had never been documented in the Western Hemisphere before the late summer of 1999, when an outbreak occurred in the New York City metropolitan area.

Disease Transmission

West Nile virus is transmitted by infected mosquitoes, which become infected after being infected wild birds—the primary hosts of the virus. The virus circulates and multiplies for several days in a mosquito’s blood before penetrating its salivary glands. After an incubation period of 10 to 14 days, an infected mosquito can transmit the virus to both humans and animals while feeding on them.

Most female mosquitoes must take a blood meal before they can lay eggs. A female’s persistent search for blood can bring it into houses and yards where it may come into contact with people. Fortunately, in areas where mosquitoes do carry the virus, very few mosquitoes are infected. See the chance of being bitten by an infected mosquito is small.

Since 2002, the Centers for Disease Control and Prevention (CDC) has confirmed additional routes of transmission, including organ transplants, blood transfusions, pregnancy (mother-to-child), and breastfeeding.

The development of vaccines provides the most feasible strategy for preventing the emergence of West Nile virus. However, as with all virus vaccines, the vaccine will not protect against all strains of West Nile virus. Therefore, the United States, in collaboration with other countries, is working to develop a single West Nile virus vaccine that will protect against all known strains of West Nile virus. The vaccine may be used to prevent infection in individuals who are at risk for exposure to West Nile virus.
The CDC is working with other agencies to track and further investigate these types of cases. Remember, the vast majority of human WNV infection occurs through the bite of a WNV-infected mosquito.

Geographic Distribution

West Nile virus was first detected in just four northeastern states in 1999. Since then, West Nile virus has been detected in wild birds, mosquitoes, horses, and humans and its distribution has continued to spread across the contiguous United States. In 2000, West Nile virus was detected in the Northeast and Mid-Atlantic states, and then in the Southeast and Midwest in 2001. By 2002, West Nile virus had reached the West Coast. In Pennsylvania, West Nile virus has been detected every year since 2000. The number of human cases in Pennsylvania peaked in 2003 at 2,377, but since then the numbers have been considerably lower (25 and fewer).

Symptoms of West Nile Encephalitis

The incubation period of a West Nile virus infection in humans is usually 3 to 14 days. Most people who are infected with the virus have either no symptoms or mild ones such as fever, headache, fatigue, body aches, and occasionally a mild skin rash or swollen lymph glands. Less than 1 percent of those infected with WNV will develop a more severe infection, which may lead to encephalitis, meningitis, meningoencephalitis, or other infections such as pneumonia. Please check with your health care provider regarding current preventative and treatment actions. Currently, many scientists are working on developing a vaccine against West Nile encephalitis.

Diagnosis and Treatment

Although there is no specific treatment, medication, or cure, the symptoms and complications of West Nile encephalitis can be treated. Serious cases may call for hospitalization, intravenous (IV) fluids, airway management, respiratory support, and treatment of secondary infections such as pneumonitis. Please check with your health care provider regarding current preventative and treatment actions. Currently, many scientists are working on developing a vaccine against West Nile encephalitis for humans.

Prevention and Control

Do not allow water to stagnate in bird baths, ornamental pools, water gardens, and swimming pools or their covers. Ornamental pools can be aerated or stocked with fish. Swimming pools should be cleaned and chlorinated when not in use.

Do not allow water to stagnate in bird baths, ornamental pools, water gardens, and swimming pools or their covers. Ornamental pools can be aerated or stocked with fish. Swimming pools should be cleaned and chlorinated when not in use.

Do not allow children to apply DEET by themselves. Do not apply a repellent directly to a child’s skin. First apply it to the palms of your own hands and then apply it to the child. Do not apply repellent to children’s hands since they may touch their eyes and mouth, causing irritation.

DEET can damage some plastics, synthetic fabrics, leather, and painted or varnished materials. DEET does not damage natural fibers such as cotton or wool.

After applying a repellent, wash or wash from your hands.

A single application of a repellent is sufficient under most conditions. Avoid prolonged or excessive use of DEET.

If a sunscreen product is needed, it should be applied first, followed by a DEET repellent product. CDC does not recommend using a combination sunscreen/DEET product.

Once indoors, wash all treated skin and clothing with soap and water. ‘‘Wet treated clothing’’ before wearing it again. If a mosquito season is occurring negatively to an insect repellent, discontinue its use, wash treated skin, and call the National Poison Center number: 1-800-222-1222. If you must see a doctor, take theDEET product.

To apply a repellent to your face, first dispense or spray it on your hands. Never apply repellent to cuts, wounds, or irritated skin. Do not put the skin or apply beneath clothing.

Use DEET Repellents Properly

DEET remains one of the most widely used insect repel- lents. Products containing 10 to 35 percent DEET will provide the greatest protection for people under most conditions. The American Academy of Pediatrics (AAP) has updated their DEET recommendations for children, citing: ‘‘Insect repellents containing DEET with a concentra- tion of 10 percent appear to be as safe as products with a concentration of 30 percent when used according to the directions on the label.’’ ‘‘A higher percentage of DEET in a repellent does not indicate better protection— nor that the protection will last longer. To use a repellent product safely, regardless of its active ingredients, follow these guidelines: ’’

● Verify that the product has an Environmental Protec- tion Agency (EPA) registration number. In presence of the label, the product is approved for use by the EPA.

● Before using any product, read and understand the directions on its label.

● Do not spray a repellent in an enclosed area or near food to which you do not inhale the aerosol particles.

● According to the AAP, DEET should not be used on infants under two months of age. Other guidelines cite not using DEET until children are two years of age.

● Use just enough repellent to lightly cover exposed skin and clothing. Never apply repellent to cuts, wounds, or irritated skin.

● Apply a repellent to your face, first dispense or spray it on your hands, and call the National Poison Center number: 1-800-222-1222. If you must see a doctor, take the repellent with you.

A very small segment of the population may be sensitive to DEET and/or other insect repellents. For more information about DEET, contact the National Pesticide Information Center at 1-800-488-7779 or your health care provider.
